

Ledger App Summary

What it is

Ledger is a Next.js 16 web app for personal finance management using Supabase. It combines dashboard, transactions, accounts, budgets, and automation settings.

Who it's for

Primary persona: people tracking personal finances; product docs/metadata mention El Salvador users.

What it does

- Email/password sign in-up via Supabase Auth; middleware protects app routes.
- Dashboard with KPI cards, charts, recent transactions, and quick actions.
- Transactions: list, search, filter, sort, paginate, and create expense-income-transfer.
- Accounts: create, edit, soft-delete, restore, and archived-view toggling.
- Budgets and sinking funds with linked goals, contributions, and monthly history.
- Automation channels for WhatsApp and email with connect/pause/resume/disconnect.
- Demo fallback mode uses local sample-data JSON when API data is unavailable.

How it works (repo evidence)

- UI: Next.js App Router pages in `app/(app)` and reusable components `/*` sections.
- Session/Auth: `@supabase/ssr` browser/server clients plus proxy middleware redirects.
- API: `/api/*` route handlers validate user then run Supabase queries and mutations.
- Data: PostgreSQL schema + RLS policies in `supabase/migrations/*`.sql.
- Data flow: page fetches API -> API hits Supabase -> JSON response -> React state.
- External bank parsing pipeline: Not found in repo.
- Production WhatsApp verification provider integration: Not found in repo (stub endpoints).

How to run (minimal)

1. Install dependencies: `npm install`
2. Add `.env` values: `NEXT_PUBLIC_SUPABASE_URL` and `NEXT_PUBLIC_SUPABASE_PUBLISHABLE_KEY`
Example values and setup details: Not found in repo.
3. Optional DB migration/seed command: Not found in repo.
4. Start app: `npm run dev`, then open `http://localhost:3000`
